COURSE, YEAR & SECTION: BSIS 2A **PROFESSOR:** Dr. GUILLERMO V. RED, Jr.

Insight Documentation Report

For this part of the project, we dug into our Student Management System database to see what the numbers could actually tell us. Instead of just storing data, we wanted to find real patterns that a school administrator might care about things like when students enroll, which courses fill up, and how much work each instructor is really handling.

First, we looked at enrollment by month. To our surprise, the numbers stayed pretty flat all year. No big registration rushes, no dead months. That tells us students are joining courses steadily, not just in traditional semester cycles. For scheduling and staffing, that kind of consistency is actually really helpful.

Next, we checked which courses are the most popular. No shock here some courses are packed, while others barely have anyone signed up. It's a classic long-tail situation. A handful of courses do the heavy lifting, and a whole lot of them just sit there with a few students. That's a sign the school might be offering more than it really needs to.

Then we looked at instructor workloads. This one made us pause. A small group of instructors are teaching a huge chunk of the total students, while others have super light loads. It's not exactly a fair distribution, and you can imagine who's feeling the burnout. A little rebalancing of course assignments could go a long way here.

We also found that the average class size is pretty small just four students per course on paper. That number backs up what we saw earlier: lots of courses, not enough students to fill them. It might be time to trim the catalog or combine some sections.

So what do we do with all this? We think a simple dashboard would make everything a lot clearer. A few key charts monthly enrollment trend, top courses bar chart, and a workload comparison would give administrators a quick, honest look at what's going on. No digging through spreadsheets required.

Overall, this activity showed us how raw database tables can turn into something useful. With a few well-written SQL queries and a little curiosity, we uncovered patterns that could actually help a school run smarter. That's a pretty cool feeling.
